ABSTRACT

The original "Bayley Scales of Infant Development" (BSID) (Bayley 1969) have been among the most popular measures of performance and aptitude of infants. In the present study the reliability and construct validity of mental and motor scores on the revised Bayley Scales of Infant Development-II (BSID-II) were investigated. A national sample of 100 children aged 2 to 42 months was used to provide data that were analyzed with second-order factor analysis. The distribution of first-order trace suggests that probably too few first-order factors have been extracted in previous research with the Bayley measures. The findings suggest that the BSID-II assesses multiple aspects of infant behavior. At the second-order level, the mental and motor scores might still emerge as discrete constructs. Results, however, are inconsistent, with discernible mental and motor dimensions in some age groups and not others. It seems that more than two second-order factors must be extracted to fully represent BSID-II score variance. Appendix A presents 16 tables of item difficulty and description data. Appendix B presents 48 tables of reliability analyses. The text contains 34 tables of analysis findings. (Contains 25 references.) (SLD)

The Validity of Mental and Motor Scores from the New Bayley Scales of Infant Development-II: A Second-Order Factor Analysis

ABSTRACT

The original Bayley Scales of Infant Development (BSID) (Bayley, 1969) have been among the most popular measures of performance and aptitude of infants. In the present study we investigated the reliability and the construct validity of mental and motor scores on the revised Bayley Scales of Infant Development-II, the BSID-II (Bayley, 1993). We employed national samples of children ranging in age from 2 to 42 months, and a variety of factor analytic methods.

The original Bayley Scales of Infant Development (BSID) (Bayley, 1969) have been among the most popular measures of infant and child cognitive development. The initial publication of the a host of investigations regarding BSID prompted characteristics of intelligence of infants ranging in age from roughly 1 to 42 months. Two parts of the original BSID--the mental scale and the motor scales -- have been the primary focus of previous Items on these two scales are scored "0" = research efforts. incorrect and "1" = correct.

Unlike the mental and the motor scales, a third part of the measure -- the Behavior Rating Scale (formerly labelled the Infant Behavior Record or IRB) -- is not a right-wrong measure. This third scale, the Behavior Rating Scale, has undergone considerably less clinical and experimental use. As noted by Matheny (1980, p. 1157) with respect to the Infant Behavior Record scale, the scale is "considered by Bayley [and others] to provide useful information about infants' developmental status, but it has not received nearly as much attention" as the more thoroughly researched mental and motor scales. Because this third scale differs from the mental and the motor scales of the BSID in its format, the Behavior Rating Scale was not evaluated as part of the present Investigations of the BSID-II Behavior Rating Scale have been reported elsewhere (cf. Wasserman, Matula & Thompson, 1993).

Efforts to understand cognitive abilities and behavior in infants is important to understanding development more generally, and studies of development may ultimately have important

implications for the ways we educate children. The revised Scales, the BSID-II, have recently been released (Bayley, 1993), and the new BSID-II will doubtless spark much research and attendant insight and controversy. The present study was conducted to explore the reliability and the construct validity of scores from the mental and the motor scales of the new BSID-II.

Our study was grounded on the philosophical premises that the business of science is formulating generalizable insight, and that no one study, taken singly, establishes the basis for such insight. As Neale and Liebert (1986, p. 290) observed:

study, however shrewdly designed carefully executed, can provide convincing support for a causal hypothesis or theoretical statement... Too many possible (if not plausible) confounds, limitations on generality, and alternative interpretations can be offered for any observation. Moreover, each of the basic methods of research (experimental, correlational, and case study) and techniques of comparison (within- or between-subjects) has intrinsic limitations. How, then, does social science theory advance through research? The answer is, by collecting a diverse evidence about any major theoretical of proposition.

In the context of the primary analytic methods that we employed-factor analyses--Gorsuch (1983, p. 201) made a related observation

that, "Factors that will appear under a wide variety of conditions are obviously more desirable than factors that appear only under specialized conditions", e.g., only when certain samples or certain factor extraction or rotation methods are used.

Given our premises, we investigated the factor structure underlying BSID-II mental and motor scales utilizing (a) national samples of subjects, (b) 16 different age groups of subjects, ranging from 2 to 42 months of age, and (c) both second-order factor analyses and several factor rotation strategies. Different though overlapping items are used at each of these ages.

Factor Analytic Research with the Original BSID Scales

The Bayley Scales of Infant Development-II (Bayley, 1993) originated in work dating back to Nancy Bayley's arrival in Berkeley at the Institute of Child Welfare in 1928. She then began a longitudinal study of 63 infants that ultimately became the impetus for the standardization of these scales. Relative to the long history of the measure, however, efforts to explore the factor structure underlying BSID scores have been limited.

Early efforts in this genre included studies by Hofstaetter (1954), Stott and Ball (1963), and McCall, Eichorn and Hogarty (1977). Findings from these earlier studies tended to suggest that different factor structures may emerge at different age levels, as a developmental dynamic. McCall et al. (1977) have suggested that empirically derived structures tend to correspond with those that might be anticipated within a Piagetian theoretical framework.

In 1967, Kohen-Raz conducted an important study involving 405

Israeli babies aged 1 to 27 months. He identified five scales that met his scaling criteria: Eye-Hand, Manipulation, Object-Relation, Imitation-Comprehension, and Vocalization-Social Contact-Active Vocabulary.

Lasky, Tyson, Rosenfeld, Priest, Krasinski, Heartwell and Gant (1983) administered the BSID to 187 "high risk" (i.e., low birth weight or required ventilator assistance) and 85 control infants. The researchers subjected a final item pool of 23 items to separate principal components analyses across the two groups and extracted five factors in both groups. They reported high congruence on the first principal component, which was the primary focus of their analysis, across these two groups.

Similarly, Barclay and McWay (1985) used principal components analysis with varimax rotation to explore the structure underlying the data from 207 "disadvantaged" infants. They isolated 4 and 6 factors across two groups of subjects. In both groups a gross psychomotor factor emerged as a dominant factor. They also a "trend toward increasing differentiation of mental abilities as a function of maturation and experience" (p. 714).

Lewis, Jaskir and Enright (1986) investigated the factor structure underlying Bayley items using data from 118 subjects measured longitudinally at ages 3, 12, 24 and 36 months. They extracted 3 or 4 factors in their analyses. They also reported what they characterized as a second-order factor solution for three age groups, and isolated two second-order factors in each of tiese analyses. However, they did not relate the second-order factors

back to the original items, as is recommended for reasonable interpretation of hierarchical factor analytic results (Gorsuch, 1983, p. 245). The researchers concluded that "the items of the Bayley do not seem to form either a strong coherent principle [sic] component or a coherent set of factors" (p. 351, emphasis in original).

Method

Sample

Our subjects were 100 infants at each of 16 different ages.

Our data were nationally sampled. Table 1 summarizes the demographic characteristics for the sample of 1,600 children who provided the data for our analyses.

INSERT TABLE 1 ABOUT HERE.

Results

Our study investigated the research question, what is the second-order factor structure underlying responses to BSID-II mental and motor scales across the 16 age groups in our samples? Many researchers acknowledge the prominent role that factor analysis can play in efforts to establish construct validity. For example, Nunnally (1978, p. 111) noted that, historically, "construct validity has been spoken of as [both] 'trait validity' and 'factorial validity.'"

Similarly, Gorsuch (1983, p. 350) noted that, "A prime use of factor analysis has been in the development of both the operational constructs for an area and the operational representatives for the

theoretical constructs." In short, "factor analysis is intimately involved with questions of validity.... Factor analysis is at the heart of the measurement of psychological constructs" (Nunnally, 1978, pp. 112-113). We employed principal components analyses for all factor extractions.

Analysts differ quite heatedly over the utility of principal components as compared to common or principal factor analysis. For example, an entire special issue on this controversy was recently published in *Multivariate Behavioral Research*. The difference between the two approaches involves the entries used on the diagonal of the correlation matrix that is analyzed—principal components analysis uses ones on the diagonal while common factor analysis uses estimates of reliability, usually estimated through an iterative process.

The two methods yield increasingly more equivalent results as either (a) the factored variables are more reliable or (b) the number of variables being factored is increased. Snook and Gorsuch (1989, p. 149) explain this second point, noting that "As the number of variables decreases, the ratio of diagonal to off-diagonal elements also decreases, and therefore the value of the communality has an increasing effect on the analysis." For example, with 10 variables the 10 diagonal entries in the correlation matrix represent 10% (10 / 100) of the 100 entries in the matrix, but with 100 variables the diagonal entries represent only 1% (100 / 10,000) of the 10,000 matrix entries. Gorsuch (1983) suggests that with 30 or more variables the differences

between solutions from the two methods are likely to be small and lead to similar interpretations.

With respect to second-order factor analysis, Kerlinger (1984) noted that, "while ordinary factor analysis is probably well understood, second-order factor analysis, a vitally important part of the analysis, seems not to be widely known and understood" (p. xivv). Example applications of second-order factor analysis have been reported by Kerlinger (1984), Thompson and Borrello (1986), Thompson and Miller (1981), and by Wasserman, Matula and Thompson (1993).

Gorsuch (1983) emphasizes that the extraction of correlated factors implies that second-order factors should be extracted. He noted, "Rotating obliquely in factor analysis implies that the factors do overlap and that there are, therefore, broader areas of generality than just a primary factor. Implicit in all oblique rotations are higher-order factors. It is recommended that these be extracted and examined..." (p. 255).

Thompson (1990, p. 575) explains second-order analysis:

Many researchers are familiar with the extraction of principal components from either a variance-covariance matrix or a correlation matrix. However, the factors extracted from such matrices can be rotated obliquely such that the rotated factors themselves are correlated. This interfactor matrix can then, in turn, also be subjected to factor analysis. These 'higher order' factors would be

termed second-order factors.

However, it is important <u>not</u> to try to interpret these secondorder factors without first relating them back to the observed variables themselves. Interpreting second-order factors only with reference to the first-order factors has been likened to interpreting shadows (second-order factors) made by other shadows (first-order factors) caused by real objects (the actual variables).

Even some very sophisticated researchers, e.g., Lewis et al. (1986) in their BSID study, incorrectly attempt to interpret the second-order factors using the first-order factors (Thompson, 1985). As Gorsuch (1983) argued,

Interpretations of the second-order factors would need to be based upon the interpretations of the first-order factors that are, in turn, based upon the interpretations of the variables... To avoid basing interpretations upon interpretations, the relationships of the original variables to each level of the higher-order factors are determined. (p. 245)

Gorsuch (1983, p. 247) suggested that one way to avoid "interpretations of interpretations" is to postmultiply the first-order factor pattern matrix times the crthogonally rotated second-order factor pattern matrix. However, if rotation is used to facilitate interpretation of other structures, it also seems plausible to rotate the product matrix itself to the varimax

criterion.

We recognized at the outset that differences in the shapes of variables' distributions will attenuate the entries in the matrix of bivariate correlation coefficients that is subjected to factor analysis (Dolenz, 1992). Therefore, in the present study we calculated item difficulty (so-called P values) and dispersion and shape statistics, as reported in Appendix A (Appendix A also presents the items used for each age group). We deemed most of the distribution shapes to be reasonably homogeneous, but clearly some of these differences always impact the relationships among dichotomously-scored achievement items.

We also recognized that score reliability can attenuate correlation coefficients (Dolenz, 1992), and that reliability is a characteristic of scores and not of tests (Thompson, 1994). Therefore, we investigated the reliability of our data. These analyses are reported in Appendix B.

For the purposes of our second-order factor analyses, we employed Guttman's (1954) criterion, and extracted all first-order factors with eigenvalues greater than 1.0. Table 2 presents the distribution of trace for all eigenvalues that were greater than 1.0, i.e., prior to rotation of the factors (Thompson, 1989). The number of first-order factors extracted in the 16 age groups ranged from 11 to 17. The Table 2 results indicate that a two-factor first-order structure would clearly be inappropriate for any of the 16 age cohorts in the present study.

INSERT TABLE 2 ABOUT HERE,

These first-order factors were rotated to the promax criterion, and the interfactor correlation matrix was analyzed and second-order factors were extracted and rotated to the varimax criterion. Here we extracted two second-order factors in each of our analyses, to allow the mental and the motor BSID-II scales to emerge as discrete entities at each age level.

First-order factors were then post-multiplied by the second-order factors, as recommended by Gorsuch (1983), and the product matrix was then rotated to the varimax criterion. These analyses were conducted with program SECONDOR (Thompson, 1990). Tables 3 through 18 present these results for the 16 age groups.

INSERT TABLES 3 THROUGH 18 ABOUT HERE.

There is another very intriguing way to interpret second-order factors that also avoids the interpretation of shadows of shadows of real objects. This is the solution proposed by Schmid and Leiman (1957), and explained by Gorsuch (1983, pp. 248-254). This solution "orthogonalizes" the two levels of analyses to each other and also allows interpretation of both levels of analysis in terms of the observed variables. Tables 19 through 34 present the Schmid-Leiman solutions, computed by program SECONDOR (Thompson, 1990), for the data from the children aged 2 to 42 months. It should be noted that the first two columns in Table 19, for example, are also equivalent to the unrotated product matrix that

Gorsuch (1983, p. 247) suggested could be interpreted without rotation.

INSERT TABLES 19 THROUGH 34 ABOUT HERE.

Discussion

Premises

Three precepts guided our interpretation of our results. First, we recognized that item or variable means do not directly affect factor structure. Factors extracted from product-moment correlation coefficients, as in the present study, are "scale-free", i.e., item means do not directly impact results. This is because product-moment correlation coefficients are themselves scale-free. For example, the correlation coefficients between all three pairs of variables (X and Y, X a id Z, Y and Z) are all +1.0, even though the means of the variables differ:

This meant that differences in items means across age groups might not necessarily create structure differences across the groups. That is, the structures might differ because relationships among variables differed, but differences in means per se do not yield such differences. If the only differences across samples are developmental delays, then structures will be comparable across

groups.

Second, we recognized that restriction of range or variability does attenuate product-moment correlation coefficients, which in turn impacts factor structure (Dolenz, 1992). If subjects in a given sample generally score near the measurement "floor" or "ceiling", then the variability of scores on items will be smaller, and correlation coefficients among these scores will be attenuated. We expected some of these effects in our samples. For example, younger subjects tend to have more homogeneous scores because ability differences have had less time to create achievement gaps across individuals.

Third, we recognized that factor order within solutions and factor scaling directions were unimportant. With respect to order, a given construct may emerge as Factor I in one sample, Factor II in another, and Factor III in yet a third sample. Small variations in the distribution of factor variance or trace (Thompson, 1989) are not noteworthy; what counts is whether the construct is reasonably stable regardless of ordering across solutions.

Also, with respect to factor scaling, we noted that the direction in which a factor is scaled is generally arbitrary. For example, in one data set the variable "handsome" may have a structure coefficient on Factor I of +.9, while "ugly" has a structure coefficient of -.8. In a second sample the signs of the coefficients may be reversed. The construct still remains a measure of attractiveness. We can always legitimately "reflect" any factor by multiplying all the coefficients on the given factor

by -1. This is legitimate because in the social science we do not presume any meaningful difference between abstract constructs scaled in different directions. For example, an achievement test can be scores number of right answers correct, or numbers of wrong answers. Thus, we did not attend to factor scaling direction differences in our interpretation.

<u>Interpretation</u>

We wanted to analyze the data with second-order factor analysis, because various levels of analysis give different perspectives on data (Gorsuch, 1983, p. 240). As Thompson (1990, p. 579) explained, "The first-order analysis is a close-up view that focuses on the details of the valleys and the peaks in mountains. The second-order analysis is like looking at the mountains at a greater distance, and yields a potentially different perspective on the mountains as constituents of a range. Both perspectives may be useful in facilitating understanding of data."

The distribution of first-order trace reported in Table 2 suggests that too few first-order factors have probably been extracted in previous research with the Bayley measures (e.g., Lewis et al., 1986). This finding suggests that the BSID-II assesses multiple aspects of infant behavior, a view that led to the construction of several theoretically- and empirically-derived Facet Scores in standard BSID-II scoring. In any case, the mental and motor scales might still emerge as discrete constructs at a second-order level.

The varimax-rotated product matrices reported in Tables 3

through 18 allow the interpretation of second-order factors in reference to the BISD-II items. The results here are inconsistent. Discernable mental and motor dimensions did emerge in some age groups (i.e., ages 2, 3, 15, 18, 24, and 27). However, at other ages the two dimensions did not emerge as discrete constructs.

The Schmid and Leiman (1957) solutions presented in Tables 19 through 34 provided yet another way to view the data. These solutions present the unrotated product matrices (as against the varimax-rotated product matrices presented in Tables 3 through 18) as the first two columns, followed by the first-order factors with all variance present in the second-order product matrices removed from these first-order matrices. Thus, the residualized first-order factors show what's left of the first-order factors, given the presence of the second-order factors. If the second-order factors perfectly reproduce the variance of a first-order factor, the residualized first-order factor will have a trace of 0.0.

With respect to the interpretability of the two second-order factors as mental and motor dimensions, based on results in the first two columns of Tables 19 through 34, these dimensions were identified in the same age groups that the two dimensions were recognizable as regards the rotated product matrices reported in Tables 3 through 18. However, the most noteworthy results from the Schmid and Leiman (1957) solutions involves the trace left in the first-order factors after the residualization process is completed. As noted, when the second-order factors reproduce most of the variance in the inter-item correlation matrix, the trace for each

residualized first-order factor will approach zero. The trace for the residualized first-order factors reported in Tables 19 through 34 suggests that, across the 16 age groups, two second-order dimensions leave considerable variance unreproduced.

This result suggests that more than two second-order factors must be extracted to fully represent BSID-II score variance. Thus, even at the second-order level, scores do not collapse into only a two-dimensional structure.

Summary

In a practical context, it is important to be able to measure abilities and behaviors of very young children, so that we may be able to identify those who may need and benefit from early intervention. In a scientific context, it is important to develop theory about the nature and the dynamics of performance as regards even very young children. Of course, deriving meaningful measurement of very young children is a daunting task.

Considerable effort has been invested in exploring the constructs measured by the Bayley Scales of Infant Development (BSID) since their original development so long ago (Bayley, 1969). The release of revised scales, BSID-II (Bayley, 1993), may facilitate even greater insight regarding dynamics within young children. The present study focused on the mental and the motor scales from the BSID-II.

From a construct validity point of view, the question is whether these results are consistent with theoretical expectations. We thought that two dimensions might emerge as second-order

factors, and that previous research with the BSID may have failed to isolate two dimensions as an artifact of methodology. However, to the extent that we did not find two-dimensional second-order structures, we thought that we would obtain increasing complex structures with increasing age, as a developmental phenomenon.

We did find increasing structural complexity with age, as reported in Table 2. There tend to be more eigenvalues greater than one with age. However, this result is confounded somewhat by the fact that different numbers of BSID-II items are used at various ages, as noted throughout the tables.

It is interesting that the mental and motor dimensions did emerge at selected ages. However, it is clear that in the aggregate a more complex structure exists even at the second-order level.

Of course, no one study establishes the construct validity of scores from any measure. It will be important to replicate these results in other samples and across various analytic methods. The use of second-order factor analyses to isolate even more complex second-order structures is especially appealing. The Table 2 results indicate that the frequent use of first-order methods in this arena may not be particularly productive in isolating parsimonious structures.

Note. The column after the orthogonalized matrix presents the sum of the squared entries in a given row. The first 2 columns represent the second order factors. The next 16 columns represent the first order solution, based on variance orthogonal to the second order (Gorsuch, 1983, pp. 248-254).
